

Take-Home: FDE Technical

Time estimate: ~2 hours (build)

Submission: GitHub repo or zip, sent before debrief

Build a lightweight app that connects **two APIs** of your choice and does something useful with the data. Deploy it somewhere publicly accessible.

Example ideas (pick one or bring your own):

- Pull open GitHub issues and post a daily digest to a Slack channel
- Query for new Opportunities created today in Salesforce and post a digest to a Slack channel
- Sync new Airtable records into a Notion database
- Watch for new Stripe payments and create a Linear ticket for each one
- Query a public weather API and trigger a webhook when conditions change

The app should also expose a webhook for external applications to hit. This endpoint should trigger a workflow that combines the integrations you've built above.

The app should ideally have an in-product flow for connecting the relevant integrations. In other words, it should be configurable to make new integration connections (e.g. to a different Slack or Github, etc) without requiring a deployment or updating static config values. The app does not need to have an explicit concept of users/tenants/orgs.

We'll be reviewing how you built it and any design decisions you took along the way.

Requirements

Core (must have):

- Authenticates with both APIs correctly
- Supports dynamic authentication with the connected systems via OAuth or similar mechanisms

- Reads data from at least one API and writes/posts to another
- Handles at least one error case gracefully (e.g. API failure, missing field, rate limit)
- Includes a README that explains: what it does, how to run it, and any assumptions you made
- Test it works on your machine before you arrive. If it requires external services, make sure those are set up and accessible on your interview day.
- **Exposes at least one HTTP endpoint** that we can hit live to trigger or inspect your integration.
 - This endpoint should accept some params that can be used to modify the behavior or the data returned
 - It should also leverage the connected systems to take some action across them.
 - It should return some data appropriate to the workflow that helps give context on what data was pulled, what actions were taken, etc.
- **Ideally it is deployed and can be triggered over the web**, this will allow us to more easily integrate with it during future exercises.

Submission

Send us a link to your repo (GitHub, GitLab, etc.) or a zip file before the debrief. Include:

- Clear instructions in your README for how to start the server and hit the endpoint locally
- Instructions on where your project is deployed and how to hit it over the web
